Key vocabulary

packet switching — Data divided into packets that may take different network routes.

circuit switching — A dedicated end-to-end circuit established before communication.

latency — Delay experienced by data in transit.

retransmission — Sending data again when loss is detected by a reliable protocol.

New learning

Packetise data — Large message split into addressed packets for shared links.

Route over network — Packets share capacity and may arrive out of order.

Reassemble reliably — TCP can reorder and retransmit data, while IP itself is best-effort.

Worked example

A 3-packet file crosses a packet-switched network. Packets arrive 2,1,3. Explain handling.

1. Send packets 1,2,3 — Identify the relevant information and make a prediction.

2. Receive 2,1,3 — Explain the change using correct technical terms.

3. Reorder 1,2,3 — Packets can follow different routes or encounter different queue delays. With a reliable transport such as TCP, sequence numbers permit correct reordering before delivery of the byte stream; missing data can be retransmitted.

We Do · Practise with guidance

A telephone system reserves capacity for a call before any voice data flows. Compare to ordinary IP networking.

Reserve dedicated circuit

Identify the relevant information and make a prediction.

Hold resources during call

Explain the change using correct technical terms.

Compare shared packet links

A circuit-switched system sets aside end-to-end resources while active; ordinary packet-switched IP shares links dynamically with others. Circuit switching offers predictable reserved capacity but can waste it during silence; packet switching adapts.

Question 1

Define packet switching and circuit switching, highlighting two differences. [6]

Question 2

Explain why packets in a message may reach the destination out of order. [6]

Question 3

Evaluate packet switching versus circuit switching for video calls, including reliability and resource efficiency. [8]

Exit Ticket · Answer before checking

IP alone guarantees that every packet is received in the original order.

You Do pages · Independent questions

Q1. Packets individually forwarded/shared links [3], circuit pre-establishes reserved route/capacity [3].

Q2. Different routes [2], variable congestion/queuing [2], sequence numbers and reliable transport reorder [2].

Q3. Shared capacity efficiency [2], delay/jitter concerns [2], circuit reservation benefits/costs [2], qualified judgement incl transport/QoS [2].

Exit Ticket · Model answer

False. IP offers best-effort delivery; transport protocols may provide ordering and retransmission.
