I Do · Read new knowledge

Key vocabulary

client-side — Execution on user device.

server-side — Execution on controlled backend.

validation — Checking input against rules.

trust boundary — Point where untrusted data enters a protected system.

New learning

Capture — HTML labels and input types structure a form.

Respond — CSS and JS can give immediate, accessible feedback.

Trust the server — Validate submission and permissions on trusted backend.

Worked example

An online form permits Years 12 or 13. Where must that rule be checked?

1. HTML accepts input — Identify the input or diagram and predict the first result.

2. Browser checks locally — Follow the second stage and explain its importance.

3. Server revalidates — HTML min/max and JavaScript improve normal experience; the server must check the supplied value independently. Client code can be changed or bypassed; no database update should trust it.

We Do · Practise with guidance

A pupil changes a visible price field before submitting checkout. How should the server protect it?

Client total altered

Identify the input or diagram and predict the first result.

Server calculates price

Follow the second stage and explain its importance.

Authorise real total

Calculate actual price using a server-controlled catalogue, validate quantity and permissions, and use authoritative stock records; never trust a submitted total.

BLACK PEN: Write your own answers. Do not look at the Review & Improve pages yet.

Question 1

Distinguish roles of HTML, CSS and JavaScript in a form. [6]

Question 2

Explain why HTML required alone does not protect database data quality. [6]

Question 3

Design an accessible 16–19 age registration flow with client and server validation. [8]

Exit Ticket · Answer before checking

A number input with min/max means a malicious client cannot submit other values.
