Key vocabulary

PageRank — Link-based iterative importance algorithm.

directed graph — Nodes joined by one-way edges.

outdegree — Number of a page's outgoing hyperlinks.

damping — Factor balancing link following and random jumping.

New learning

Build graph — Web pages are vertices; directed hyperlinks are edges.

Distribute rank — Each page shares rank across its outgoing links.

Apply damping — PRnew=(1-d)/N+d×sum(incoming PR/outdegree).

Worked example

A→B,C; B→C; C→A. Initially PR(A)=PR(B)=PR(C)=1/3; d=0.85. Calculate one iteration.

1. A→B,C | B→C | C→A — Identify the input or diagram and predict the first result.

2. Incoming shares 1/3,1/6,1/2 — Follow the second stage and explain its importance.

3. Result .333,.192,.475 — Incoming shares A:1/3; B:1/6; C:1/6+1/3=1/2. Base (1-.85)/3=.05. New A=.3333, B=.1917, C=.4750, sum=1.0000.

We Do · Practise with guidance

A→B; B→A,C; C→A; equal initial rank and d=0.85. Which page ranks highest after one update?

A→B | B→A,C | C→A

Identify the input or diagram and predict the first result.

Shares 1/2,1/3,1/6

Follow the second stage and explain its importance.

A=.475 highest

Incoming contributions A=1/6+1/3=1/2, B=1/3, C=1/6. Add base 0.05 and scale by 0.85: A=.4750, B=.3333, C=.1917. A ranks highest.

Question 1

Explain how PageRank uses inbound links and outbound link counts. [6]

Question 2

A page of rank 0.40 has two outgoing links. What undamped contribution goes down each? [4]

Question 3

Compute one PageRank update for A→B,C B→C C→A with equal initial ranks and d=.85, then explain an important limitation. [8]

Exit Ticket · Answer before checking

With PageRank a page with two outgoing links shares its current rank equally between them in the simplified model.
