Now change to GREEN PEN. Find each original question. Tick correct answers; read the model and rewrite mistakes.

Page 1 onwards · Do Now

Q1. Requested item found in cache.

Q2. A unit of processor clock timing.

Q3. An independent CPU execution unit.

Q4. 64→32→16→8→4→2→1; six halvings.

You Do pages · Independent questions

Q1. Clock affects cycles/sec [2], cores parallel tasks [2], cache reduces slower memory accesses [2].

Q2. 3/2=1.5 [2], Y50% more cycles/s [2], memory stalls/parallelisation or instruction mix [2].

Q3. Rendering often exploits cores [2], sequential script needs stronger single-thread performance [2], cache/IPC/workload caveats [2].

Exit Ticket · Model answer

False. Clock speed alone does not determine total performance.

Try the question again

Choose one question you got wrong. All correct? Choose the hardest.

I Do · Read new knowledge

Key vocabulary

GHz — Billions of cycles per second.

core — CPU execution core.

cache hit — Data found in CPU cache.

IPC — Instructions retired per cycle (workload dependent).

New learning

Observe — Clock speed counts clock cycles per second; one cycle is not always one complete instruction. Frequency alone cannot predict program performance.

Explain — Multiple CPU cores improve performance most for work divided into independently executable threads; a strictly sequential task may gain little.

Evaluate — Cache is small, fast storage close to CPU. A cache hit avoids some slower RAM accesses; cache size, locality and hit rate influence results.

Worked example

Compare 2 GHz and 3 GHz clock rates under equal work per clock and no bottlenecks.

1. Explain the mechanism — 3 GHz offers 50% more cycles each second than2 GHz; this does not universally imply 50% faster program runtime. — The comparison requires equal microarchitecture and workload assumptions.

We Do · Practise with guidance

A single-threaded algorithm runs on a 2-core or 8-core CPU of equal per-core performance. Explain likely benefit.

Explain the mechanism

It may not be substantially faster from extra cores alone; only one thread is the bottleneck.

Parallel benefits need tasks/threads that can run concurrently.

Question 1

Explain effects of clock speed, number of cores and cache on performance. [6]

Question 2

CPU X 2GHz and Y 3GHz have identical IPC; compute ratio of cycles/sec and one reason runtime may differ from ratio. [6]

Question 3

Recommend improvements for school video rendering versus a sequential exam-marking script. Discuss CPU performance factors. [6]

Exit Ticket · Answer before checking

A 4GHz processor always completes any program twice as fast as a 2GHz processor.
